Andre's Distribution

In the keynote presented by Jensen Huang at NVIDIA GTC 2026, Jensen opened by celebrating 20 years of CUDA and set an ambitious tone by projecting \$1 trillion in purchase orders for Blackwell and Vera Rubin systems through 2027. The keynote was mainly about the rapid growth of AI and how it is driving the need for more advanced computing systems. I learned that NVIDIA is developing new technologies like the Vera Rubin architecture, a massive system that promises much better performance and efficiency, as well as partnerships like the one with Groq to improve processing power. What is new is the scale of these advancements and how quickly AI infrastructure is evolving, showing that we are entering a new era of computing with much more powerful systems than before.

Eva's Distribution

The session *Agentic AI 101* was about how artificial intelligence is evolving into more advanced systems called agentic AI, which can act independently rather than just respond to prompts. I learned that AI has rapidly developed over the past few years, starting with tools like ChatGPT and moving toward models that can reason, break down problems, and create solutions. The session explained how AI agents work as complex systems that include memory, multimodal inputs, tools, and even sub-agents that collaborate to complete tasks. One example that stood out was how companies like ServiceNow use multi-agent systems to automatically handle customer service tickets, resolving up to 90% of them without human intervention. What is new about this technology is the idea of AI agents working autonomously and even collaborating with other agents, which makes them much more powerful than traditional chatbots. This shows that AI is becoming more capable of handling complex, real-world tasks and will play a major role in improving efficiency across different industries.

Muhammad's Distribution

The robotics sessions at NVIDIA GTC 2026 mainly focused on how AI is being used to make robots smarter and more useful in real-world situations. A big theme was physical AI, where robots are trained to interact with the real-world using simulation before being deployed. NVIDIA showed how digital twins and simulated environments are helping robots learn faster without needing as much real-world testing. There was also a focus on humanoid robots and how new AI models are being developed specifically for robotics tasks like movement, vision, and decision-making. Another important point was the use of synthetic data, and something called a physical AI data factory, which helps generate large amounts of data to train robots more efficiently. Overall, the session showed that robotics is moving beyond basic automation and becoming more intelligent and adaptive, but it's still developing and not fully ready for real-world use yet.

The process

Our team approached this assignment by first registering for the NVIDIA GTC conference and creating NVIDIA Developer accounts to access the recorded sessions. We started by reviewing the keynote by Jensen Huang to understand the main ideas and current trends in artificial intelligence. After that, each team member selected a different session based on their interests to ensure we covered a variety of topics without overlapping. We took notes individually while watching our sessions, focusing on what the session was about, what we learned, and what was new. Finally, we combined our responses into one document and reviewed everything together to make sure it was clear and complete.
